Correspondence Audit Studies in Public Administration: A Systematic Review with Commentary

Ryan A. Beasley*, Joanna N. Lahey†

Abstract: Correspondence audit studies are becoming more prevalent in the field of Public Administration (PA). We explain the benefits and limitations of audit studies and provide a systematic literature review of PA audit studies. Our systematic review includes journal articles written in English and containing audit studies in PA that were gathered from highly ranked PA journals, and also forward and reverse citations of relevant prominent articles. We summarize the frequency of topics and other selected aspects of the 90 included articles. We then discuss common concerns with audit studies both in PA and more generally. Finally, we discuss future directions for these kinds of studies that go beyond the standard measures of discrimination between two groups.

Keywords: Audit Studies, Correspondence Reviews, Systematic Literature Review, Public Administration

An audit study, sometimes called a correspondence audit or correspondence review, is a form of field experiment in which the researcher sends out treatment and control stimuli, often written, to real participants who do not realize they are being studied. The researcher then measures differences in responses for the different treatments. Audit studies were pioneered in the mid-20th century to study discrimination in housing and labor markets (Fix & Struyk 1993). In these original studies, researchers followed up correspondence with pairs of in-person actors chosen and trained to be as identical as possible except for the group characteristic being studied, for example, race. Today in-person audits are rare, but correspondence audits have been growing in popularity across many disciplines (Gaddis 2018). Modern audits utilize new techniques to better study the market, such as investigating interaction effects between stimuli characteristics and presenting stimuli via a variety of digital media. Given the large size of many modern audits, researchers are less likely to send pairs of stimuli which are identical except the item being studied. Additionally, while early audit studies usually focused on race discrimination, modern researchers use audits to study any outcome that involves differential treatment.

This emphasis on hypothetical stimuli sent to real participants who 1. make real decisions, and 2. do not know that they are being studied, is what sets audit studies apart from other A/B style field experiments. Audit studies are not surveys or survey experiments in which the participants know their responses are being studied. They do not involve providing vignettes and asking for hypothetical choices. They do not use a student sample as a substitute for non-student decision-makers. The benefit to these restrictions is that well designed audits provide information about how actual constituents respond in real market environments. That said, it can be difficult to determine whether certain field experiments should be classified as correspondence or audit studies. For the purposes of this review, we are defining audit studies as studies that attempt to *measure* behavior, not to *change* behavior. Examples of attempting to change behavior (thus are not audit studies) include experiments that nudge taxpayers into paying real tax bills (John & Blume 2018), vary

advertising messages to recruit police applicants (Linos 2018), or change stimuli presented in Facebook ads to see how they can affect future polls (Broockman & Green 2014).

The primary benefit of audit studies is that, unlike cross-sectional studies using large datasets, they can measure behavior at the partial equilibrium level rather than the total equilibrium. In other words, audit studies can measure discrimination as it occurs at the application level between otherwise identical applicants. The final outcome of any market includes selection, in which people avoid applying to places in which they believe there is discrimination, or in which people who are discriminated against must spend additional effort compared to those who are not; thus studies that look only at the final outcome may miss discriminatory behavior. Additionally, in many markets, the average characteristics of the different groups of applicants are not identical, so without an audit study, it is unclear whether general equilibrium differences in outcomes are caused by discrimination or by differences in the applicants themselves. Audit studies bypass both of these problems.

While the audit study is a powerful research method, it has limitations. First, audit studies generally do not measure the last step in a multi-stage process. For example, if measuring discrimination in labor markets, they only measure whether a hypothetical applicant is called in for an interview, not if the applicant receives a job offer. If discrimination increases or decreases at later stages in the process, audit studies are unlikely to pick up these differences. However, treatment at this first stage is important by itself: one cannot get to the second stage without passing the first stage. Many Public Administration (PA) studies do not have this limitation because they focus on one-stage processes such as one-time requests for information to government officials. However, even these studies have the problem that without being able to see the entire market; it is unclear whether, for example, Republicans tend to be more responsive than Democrats to constituent stimuli (Hayes & Bishin 2020; Janusz & Lajevardi 2016) because they have more responsive natures or because they get fewer requests.

Another limitation of the audit study is that they are only externally valid for the stimuli that they send. Lahey & Beasley (2009) coined the term “template bias” to describe one aspect of this problem. Template bias occurs when a limited number of stimulus templates are sent out that do not represent sufficient variation. For example, assume a hypothetical labor market in which Hispanic men are only discriminated against if they have mustaches, while non-Hispanic men with mustaches are not discriminated against. If only auditors without mustaches are sent to apply for jobs, this underlying discrimination will not be found. Ideally an audit study will send stimuli that fully explore the feature variation seen in the market and relevant to the study topic.

Finally, audit studies tend to be limited to brief interactions and limited outcome variables; they generally measure the outcomes of the first stage of an application process or a brief request for information. Unlike a survey, focus group, or other more in-depth approach, audit studies cannot collect information on counterfactuals and are generally limited to what demographic information is publicly available. There are some exceptions that combine an audit study with another form of experimental design, but these are rare (Dynes et al. 2021; Rooth 2010). Similarly, audit studies are unable to include all possible participant characteristics; for external validity, they can only present stimuli that could be seen in the market.

The audit study method is gaining in popularity for gathering evidence related to PA hypotheses and models, and while systematic reviews have been done on the more general domain of PA field experiments (Bouwman & Grimmelikhuijsen 2016; Hansen & Tummers 2020; Li & Ryzin 2017), this is the first effort to systematically review audit studies and correspondence reviews in PA (Public Administration, Public Policy, and relevant Political Science academic journals). By systematically reviewing these studies, we hope to provide an overview of the innovations that PA has brought to audit studies (in outcomes, inputs, and participants), as well as a starting point for new practitioners.ⁱ We refer readers interested in how to do an audit study to the Lahey & Beasley (2018) chapter in Gaddis (2018).

Systematic Literature Review Methods

The eligibility criteria for this systematic literature review are Public Administration research articles published in peer-reviewed academic journals. Only English articles were included. Any publication date was eligible, with new papers gathered through May 2021.ⁱⁱ The only eligible study designs were audit studies or

correspondence reviews in which the participants performed a real task, i.e., a typical action they might perform such as one of the expected tasks of their job, and were unaware of their study participation while doing so. The participants, tasks, and/or theoretical framework must have been relevant to Public Administration, broadly defined.

Articles were gathered from specified journals, papers cited by selected systematic literature reviews, and forward and backward citations. We first searched the top 50 journals ordered by Scimago Journal Rank (SJR) indicator, from the Scimago Journal & Country Rank website under the subject area “Public Administration” [<https://www.scimagojr.com/journalrank.php?category=3321> last accessed 5/13/21]. We searched each journal via its website for ("Audit" AND "Experiment") OR ("Correspondence" AND "Experiment"). Additionally, we gathered papers that cite, or are cited by, three systematic literature reviews on experimental studies in PA (Bouwman & Grimmelikhuijsen 2016; Hansen & Tummers 2020; Li & Ryzin 2017). We also gathered relevant papers that cite, or are cited by, papers collected from the above sources that had particularly impressive literature reviews or seemed to be cited by many papers (Adman & Jansson 2017; Broockman 2013; Costa 2017; Landgrave 2020; Margetts 2011).

As the papers were collected, they went through an exclusion screen to remove papers that were 1. Not an experiment, 2. A survey, vignette, or other hypothetical experiment in which participants know they are being studied, 3. Not Public Administration, and 4. Trying to change behavior (beyond any immediate response to the stimuli) rather than just measuring it. Two reviewers, one PhD coauthor and one graduate research assistant, worked independently to determine which studies met the inclusion criteria. Reviewers read the title and abstract and when the abstract did not provide enough information, they read the paper itself. Questions and disagreements were handled by discussion with the other PhD coauthor. On a regular basis an additional graduate research assistant compared the lists from the two reviewers, and the team then met to discuss any discrepancies between the lists.

Several RAs worked independently to pull information out of the papers for summary statistics. Each included paper had two to three research assistants separately screening for characteristics. Any discrepancies were brought to the attention of the authors who made final decisions on any disagreements. Table 1 contains the aspects that were coded for each article broken apart by participant type. With some important exceptions, it appears that there are more similarities than differences between studies of street-level bureaucrats and elites, so we will generally be discussing studies with all types of participants together, pointing out some important differences in the discussion.

Table 1: Study design features

Study design features	Participants			
	Street-level bureaucrats	Political Elites	Other	Total
<u>Participant</u>				
Ideological families or political parties	4	23	4	31
Gender	1	14	2	17
Race or ethnicity	2	8	5	15
Job security	0	10	0	10
Country	1	2	2	5
Pre-election vs post-election	0	2	2	4
Methods of election (e.g., nominal vs party list)	0	4	0	4
Status of being impacted by political mandates or antidiscrimination policies	1	0	1	2
<u>Stimuli</u>				
Race or ethnicity	14	21	10	45
Gender	7	16	2	25
Tone or consequences of request (including FOIA)	9	7	3	19
Socio-economic status	5	7	3	15
Political party	2	7	2	11
Constituency	1	8	1	10
Personal vote intentions	0	6	0	6
Religion	2	3	0	5
Social or peer pressure	3	2	0	5
Incentivization of participation	1	2	1	4
Citizenship	0	2	1	3
Policy requests vs service requests	0	2	1	3
Inclusion of information about policies in other countries/states/areas	1	1	1	3
Political donor statement	0	2	0	2
Same-sex partner	1	0	0	1
<u>Analysis</u>				
Between-subjects	26	36	15	77
Standard OLS/logit/probit regression	23	31	17	71
Evaluates the quality or speed of responses	23	26	12	61
Interaction effects (e.g., writer's race vs the participant's party)	9	14	4	27
Within-subjects	3	7	3	13
Includes a power analysis	3	4	1	8
Effect of an initial stimulus on a later stimulus	1	1	0	2

Note: Other includes both elected officials and street-level bureaucrats in the same study (4), employers (3), universities (2), potential voters (1), nursing homes (1), salespeople (1), landlords (1), Facebook users (1), citizens (1), and other private/non-profit services (3). (If the participant was not a public official, the stimulus was related to public affairs writ large.)

Systematic Literature Review Results

Our systematic literature review identified a total of 2076 references: 1282 through the journal search, 255 from the previous systematic literature reviews, and 539 through cited or citing reference searches, as shown in Figure 1.ⁱⁱⁱ We excluded 1986 references. A total of 90 journal articles are included in the results below. As noted earlier, we excluded Broockman & Green (2014), John & Blume (2018), and Linos (2018) because they attempted to change behavior rather than just measure it. We included Michelson (2006), on the other hand, because some of the analysis is on whether canvassers were able to contact participants, even though the rest of the study (whether the participants voted at a later date) was about changing behavior. Similarly, we included Butler & Crabtree (2017) even though it measured the behavioral impact of receiving an information treatment at an earlier date, because two-thirds of the participants did not receive that information and results were reported separately by group. We included Jilke et al. (2019) because it manipulated information cues to test immediate behavior, not to influence future behavior. For a tricky example of participants knowing they were in an experiment, we excluded Nyhan & Reifler (2015) because the participants in the placebo group were sent a letter informing them about the experiment and their results combine the placebo and treatment groups. We were generous in our inclusion of which papers were of interest to PA, including papers from our list of journals such as Darolia et al. (2015), published in the *Journal of Policy Analysis and Management*, which studies whether employers prefer workers from for-profit vs. not-for-profit colleges. We also included papers studying politicians. We excluded Schultz, Khazian, & Zaleski (2008), which was cited in a prominent paper, but was published in a psychology journal, because its topic of promoting conservation among hotel guests is not PA. Our exclusion of non-audit papers also meant that we excluded papers that analyze already gathered data, e.g., Lowande, Ritchie, & Lauterbach (2019).

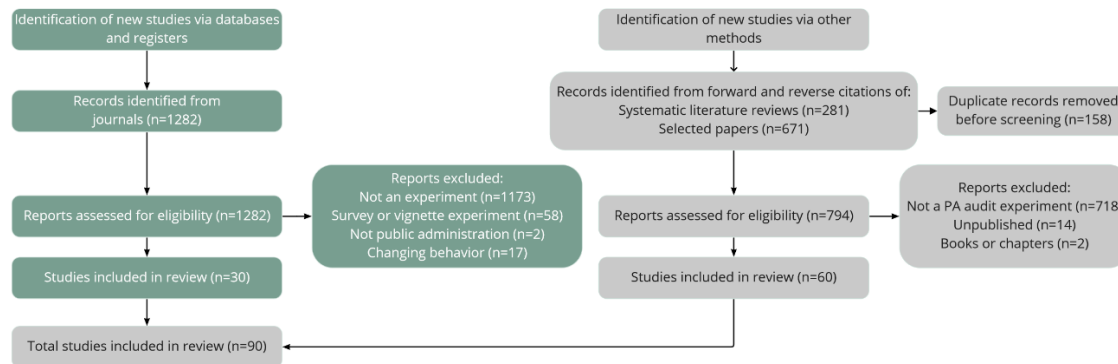

Figure 1: Consort diagram

In the past two decades, 90 PA journal articles that use audit studies have been published, with the rate of publication rapidly increasing over the past decade, shown in Figure 2. The studies were gathered from 47 journals, 15 of which published more than one PA audit study, shown in Table 2. These studies were performed in many countries: Argentina, Austria, Belgium, Brazil, Canada, Chile, China, Colombia, Denmark, England, Estonia, Finland, France, Germany, Hungary, India, Ireland, Italy, Mexico, Netherlands, New Zealand, Russia, Slovakia, South Africa, Sweden, Switzerland, Taiwan, United Kingdom, United States of America, and Uruguay.

Notes: Journals with exactly one included publication: Administrative Science Quarterly; British Journal of Political Science; China Quarterly; Cogent Social Sciences; Criminology & Public Policy; Democratization; Indian Review; International Interactions; Journal of Civil Society; Journal of Comparative Economics; Journal of Law and Economics; Journal of Policy Analysis and Management, Journal of Race, Ethnicity, and Politics; Journal of the European Economic Association; Local Government Studies; New Media and Society; Parliamentary Affairs; Party Politics; Perspectives on Politics; PLOS ONE; Political Analysis; Political Psychology; Political Science; Political Science Research & Methods; Politics & Gender; Politics, Groups, and Identities; Proceedings of the National Academy of Sciences; Public Administration; Quarterly Journal of Political Science; Regulation & Governance; Social Science Journal; State Politics & Policy Quarterly. See Table 1 for additional notes.

Figure 2: Year of publication

Who is Studied and How?

A distinguishing feature of PA audit studies is the typical participant pool: elected and appointed officials or their constituents. Some studies include a wide variety of officials, but many focus on a specific subset, such as politicians, front-line street-level bureaucrats, or back-office administrators. This participant pool differs from those used in economics and sociology which are more likely to focus on labor, mortgage and rental markets (see Gaddis 2018 for a literature review), or the emerging public health literature on customer service (e.g., Button et al. 2020; Mackenzie-Liu et al. 2020). Overall, 43 of these studies focus on political elites, 29 on bureaucrats, and 18 have participants who do not belong to one of these groups (but some other aspect of the study makes it of interest to public administration researchers), as shown in Table 3.

Table 3 also presents the different outcomes studied in PA correspondence studies. The most popular topic for these studies in PA (43% of included papers) is the responsiveness of political elites to unofficial requests for information. Another popular area of study instead investigates the responsiveness of street-level and frontline bureaucrats to different constituent characteristics (23%, e.g., Adman & Jansson 2017; Distelhorst & Hou 2014; Einstein & Glick 2017; Grohs et al. 2016; Michener et al. 2020). Nearly as popular (14%) is another type of study in which researchers present freedom-of-information act (FOIA) requests varying tone, information provided, and writer characteristics such as political donations or demographic characteristics (e.g., Ben-Aaron et al. 2017; Jenkins et al. 2020; Lagunes & Pocasangre 2019; Michener et al. 2020; Peisakhin 2012; Spáč et al. 2018). While some papers study job callbacks (Darolia et al. 2015; Hou et al. 2020; Kang et al. 2016; Vuolo et al. 2017), they are uncommon (4%), particularly compared to audit studies done by sociologists and economists (see Gaddis 2018 for a literature review and Lippens et al. 2023 for a meta-analysis)^{iv}.

Table 3: Outcomes of interest

		Participants			
		Street-level bureaucrats	Political Elites	Other	Total
Outcome	Responsiveness to unofficial request	21	39	6	66
	Responsiveness to FOIA request	7	3	3	13
	Callbacks to job applications			4	4
	Other	1	1	5	7
Total		29	43	18	90

Note: Other Outcome includes voter turnout, ID declination, charitable donations, willingness to participate in a survey, rental approvals, and offers of investment incentives. FOIA row includes other (non-US/state) official freedom of information/public records act requests. See Table 1 for additional notes.

PA audit studies often explore how participant responses vary with respect to participant characteristics, for example, do participants from different demographic or political groups respond differently to stimuli. Many experiments have analyzed differences with respect to the participant's race and ethnicity (17%, Broockman 2013; Butler & Broockman 2011; Gaikwad & Nellis 2021; Habel & Birch 2019; McClendon 2016; Mendez & Grose 2018; Newland & Liu 2021; Vaishnav, Khosla, Milliff, & Osnos 2019) or the participant's gender (19%, Dhima 2022; Magni & Ponce de Leon 2021; Rhinehart 2020; Thomsen & Sanders 2020). Responses have been compared between participants from different ideological families or political parties (34%, Butler, Karpowitz, & Pope 2012; Dropp & Peskowitz 2012; Gell-Redman et al. 2018; Hayes & Bishin 2020; Porter & Rogowski 2018). The response rates of legislators (political elites) have been examined as a function of their job security (11%, Dropp & Peskowitz 2012; Giger et al. 2020), and pre-election vs post-election timing (4%, Driscoll, Cepaluni, Guimarães, & Spada 2018). Similarly, the behaviors of nominally-elected legislators have been compared with those elected via party list (4%, Bol 2021). The hiring practices of firms impacted by political mandates have been compared with firms free of such mandates (Hou, Liu, & Crabtree 2020), and the responsiveness of participants affected by antidiscrimination policies have been compared with participants not affected by such (2%, White, Nathan, & Fallor 2015). Responses by local municipal officials have been compared across countries (Butler, De Vries, & Solaz 2019). Incorporating participant characteristics as these studies do enables testing of more nuanced models of behavior, often detecting heterogeneous behavior between subpopulations of participants, and occasionally showing that all the detected discrimination from the participants is coming from such a subpopulation (e.g. Mendez & Grose 2018).

Stimuli signals

As is common in other fields, many PA audit studies vary the stimuli to signal differences in the hypothetical writer's race or ethnicity (50%, Butler & Broockman 2011; Landgrave 2021; Newland & Liu 2021; Olsen et al. 2022), gender (28%, Golder et al. 2019; Kalla et al. 2018; Magni & Ponce de Leon 2021), socio-economic status (17%, Hayes & Bishin 2020; Taghizadeh et al. 2022), and religion (6%, Crawford & Ramli 2022; Lajevardi 2020; Pfaff et al. 2021; Vaishnav et al. 2019). For the most part, studies on ethnicity, gender, immigrants, race, and religion find discrimination against females and minorities, both in response rate and response quality. However, the subset of studies in which stimuli include political aspirants asking for guidance generally present pro-women results (e.g., Rhinehart 2020; Dhima 2020). Additionally, a small number of non-US studies do not find discrimination (e.g., Newland & Liu 2021; Taghizadeh et al. 2022), or in one case find pro-women results (Magni & Ponce de Leon 2021). Discrimination can be reduced by suggesting that the participant's

responses may be publicized (Landgrave 2020), or by contacting political candidates in the time leading up to elections (Driscoll et al. 2018). Like other discrimination studies, studies on schools found religious/political/racial discrimination by officials, though Block et al. (2021) shows that racial discrimination found in higher education is less than what is found in the general public. In comparison, studies investigating SES and education have provided mixed results. Some show that stimuli indicating lower class/education get fewer responses (Landgrave & Weller 2022; Michener et al. 2020; Neiman 2017; Peisakhin 2012; Taghizadeh 2021), while others show no evidence of bias (Carnes & Holbein 2019; Hayes & Bishin 2020; Lajevardi 2020). Unlike audits in labor economics, age-based signals are not yet a focus of studies in PA.

Other PA studies vary their stimuli in more novel ways.^v Studies find no effect of citizenship status when SES is controlled for (Alizade et al. 2021; Landgrave & Weller 2022; Newland & Liu 2021). They find that political elites are more helpful for constituents compared to non-constituents (Loewen & MacKenzie 2019). Senior policymakers made themselves available 3-4 times more often for political donors (Kalla & Broockman 2016). Legislators are more likely to respond when the stimuli include an intention for personal voting instead of partisan voting (Bol et al. 2021). Finally, bureaucrats provisioning marriage licenses show no evidence of discrimination against same-sex partners (Lowande & Proctor 2020).

Beyond the hypothetical writer's characteristics, PA studies have also varied stimuli characteristics. For example, offices are more responsive to service requests than to requests about policy (Butler, Karpowitz, & Pope 2012). Compliance is increased by peer effects, but unaffected or reduced by shaming (Ben-Aaron et al. 2017; Terechshenko et al. 2019). When provided with information about implemented policies, local European officials are not biased against foreign policy information (Butler et al. 2019). Finally, legislators asked to take a survey and incentivized by a donation to a charity for college students are less likely to participate if the donation is for Hispanic students than for students of unspecified ethnicity, but the discrimination is mitigated if the stimulus says the donation will be made public knowledge (Landgrave 2020).

A growing subfield of PA experiments investigates how officials respond to the "tone" of a stimulus or to potential consequences (21%, Chen, Pan, & Xu 2016). Those stimuli often include official requests under freedom-of-information laws (14%, Lagunes & Pocasangre 2019; Michener et al. 2020; Rodríguez & Rossel 2018; Spáč et al. 2018; Worthy et al. 2017). Peisakhin (2012) even compared requests made under such laws with requests accompanied by bribes. Most of these studies find that freedom-of-information laws are beneficial, with different studies looking into different aspects leading to responsiveness; for example, larger municipalities are more responsive (Spáč et al. 2018), the strongest effect is on concordance (not compliance) (Grimmelikhuijsen et al. 2019), stating the law is only for male requestors (Rodríguez & Rossel 2018), and formal requests almost erase class differences (Peisakhin 2012).

Beyond the effects of either stimulus or participant characteristics on outcomes of interest, interactions between those characteristics can have important effects on outcomes. 30% of included papers analyze interaction effects. Discrimination is found in the interaction between ethnicity and either occupation (Habel & Birch 2019) or gender (Grohs et al. 2016). PA audits have studied in-group vs out-group association for ethnicity with local officials less likely to assist outgroup members (Distelhorst & Hou 2014), race with politicians more responsive to same-race constituents (McClendon 2016), gender with legislators more responsive to female political aspirants (Dhima 2020; Rhinehart 2020), and political party where political party of stimulus does not mitigate racial bias exhibited by political elites, while local election clerks are more responsive to co-partisan stimuli (Butler & Broockman 2011; Porter & Rogowski 2018). The intrinsic vs extrinsic motivation of the participant has been investigated via interaction effects between constituency and electoral safety—responsiveness to constituents is even higher with electoral competition (Giger et al. 2020), and between constituency and the participant's race with Black legislators more motivated than non-Black legislators to respond to Black non-constituents (Broockman 2013). Discrimination against stimuli signaling different races and ethnicities has been studied via various interaction effects, for example, whether discrimination against Hispanics is driven by Republican legislators (Gell-Redman et al. 2018), participants supporting voter identification laws are less responsive to Latino stimuli (Mendez & Grose 2018), and bias against Latinos is lower in jurisdictions covered by antidiscrimination policies (White, Nathan, & Faller 2015). These studies show that interactions between characteristics can be necessary factors in understanding experimental results.

Study design and analysis

Along with identifying the participant pool and crafting stimuli content, two important study design questions are how many stimuli to send to each participant, and which medium to use for communication. With any within-subject design, a participant may directly compare stimuli, leading to them treating the stimuli differently than they would have in the absence of the comparison. Indeed, there is direct evidence of spillover effects within audit studies with multiple stimuli sent to each participant (Phillips 2019). In a field experiment such as a correspondence audit, there may be additional concerns about the participant realizing that they in an experiment should they receive multiple similar stimuli, and multiple stimuli mean that the participant may be more likely to treat the hypothetical information as real information, which could affect their beliefs and decisions. The majority of included papers use between-subjects studies (86%); 81% of the papers sent a single stimulus to each participant. The stimuli medium can also result in different levels of responsiveness and response quality (Epstein et al. 2021). The majority of PA audit studies (88%) send stimuli via email due to its ease and minimal expense. Notable alternatives include in-person audits (7%; Ernst, Nguyen, & Taylor 2013), physical letters (6%; Butler, Karpowitz, & Pope 2012), and online forum posts or other website use (7%; Chen et al. 2016; Jilke et al. 2019). Phone calls are uncommon (3%). 10% of the studies incorporate multiple communication media.

Many studies (69%) include multiple outcomes of interest, with (68%) analyzing response rates plus various measures of the quality of response (Hemker & Rink 2017; White et al. 2015; Worthy et al. 2017). See Costa (2020) for a study on what alters the quality of responses, and Coppock (2019) for a short discussion on how to handle non-responses and avoid post-treatment bias.^{vi} Only 9% of papers include a power analysis to show the smallest effect size that could have been detected (Landgrave 2020).

Innovations

PA as a field has brought broad innovations to the audit literature. Rather than focusing on labor and housing markets, PA has leveraged this technology to investigate important questions about the responsiveness of public servants, including responsiveness to FOIA requests. Another broad innovation stems from PA audits often knowing participant characteristics (particularly in the case of political elites), unlike many economics and sociology audits where an employment firm or housing address may be known, but the actual person making the decisions is unknown. That means that not only can PA audits determine differences in treatment by participant characteristics, but they can also study in-group vs. out-group differences and match participant and stimulus on demographic characteristics.

In addition to the general innovations of PA audit studies, during our systematic literature review we came across PA papers that we found to be particularly innovative. Multiple studies have been designed to accomplish two tasks simultaneously. Similarly to some FOIA audits (e.g., Jenkins et al. 2020; Spáč et al. 2018), Grose et al. (2015) directly used the responses to the stimuli in a follow-on study, by surveying how constituents reacted to actual legislator messaging. Both Block et al. (2021) and Landgrave (2020) did audit studies to see who would participate in surveys, but Landgrave additionally used the parameters of the survey incentivization (the specific recipient of the donation and the donation publicity/anonymity) as independent variables in the audit study. Vuolo et al. (2017) combined a job application audit study with an analysis of the calls for applications. Peisakhin & Pinto (2010) provided social benefit with their audit study by recruiting confederates that might materially benefit from participation.

Some of the included PA audit studies innovated study design and analysis. Innovative outcome variables include Butler & Crabtree (2017) and Butler et al. (2019) which study whether emailed stimuli were opened, something Hughes et al. (2020) claims is a metric of implicit discrimination. Butler et al. (2019) further tracked whether participants followed emailed links to additional information. As another example, Lagues & Pocasangre (2019) repeated the same FOIA audit study over multiple years and found changes in responsiveness over time.

More than one study tested innovative interactions. For example, Giger et al. (2020) and Broockman (2013) tested intrinsic vs extrinsic motivation in political elites by varying the constituency or jurisdiction conveyed by the stimuli. Michener et al. (2020) discovered that response rate depended on whether the putative stimuli writers were discoverable via websearch. Taghizadeh (2021) interacted ethnic signals in the stimuli

with participants' caseloads to investigate the effects of workload on discrimination. Similarly, Habel & Birch (2019) found an interaction effect between occupation and ethnicity. Block et al. (2021) included officials and members of the general population, enabling comparison of their discrimination in responding.

In another example of innovation, Epstein et al. (2021) compared municipality responses by stimulus medium (email vs Twitter) and found differences in responsiveness and quality, making the point that studies will have to adapt as new media grow in public usage.

Additional concerns

In this section, we provide additional considerations not mentioned above. Our purpose is not to confront the PA literature, but instead to provide areas for PA researchers to think about. Although many audit studies do an excellent job of beginning from a theoretical or policy-relevant framework, as James et al. (2017) note in their book chapter on public management field experiments generally, some studies do not. James et al. (2017) also note that formal theoretical foundations are not always necessary and that results from field experiments can be used to formulate new theory. However, experiments are best when they are well thought out and are guided by at least informal theoretical considerations.

It is important for authors to do and present preliminary power calculations prior to sending out a study. This need is particularly important when the study finds null results, as insignificant results could be caused by insufficient sample size. In addition, audit studies that send multiple treatments to participants need to be sure to adjust their sample size calculations for clustering, as unadjusted size sample size calculations will provide too small a sample (see Lahey & Beasley 2018). And, as with all experiments, power calculations that intend to include interaction terms may need to more than double the single term sample size to get the correct power (see Giner-Soralla, 2018 for an excellent discussion of heuristics for interaction terms). It is concerning that less than 10% of the audit studies we found in the systematic review mentioned these calculations.

Two sources of internal validity concerns must be addressed when multiple stimuli are sent to the same participant. First, naively sending similar stimuli to a broader collection of participants could result in participants getting unusual stimuli (ex. correspondence from Black constituents when such correspondence is rare) that causes them to either suspect they are in an experiment or to form false beliefs about their constituent needs. A second internal validity concern arises when a participant compares stimuli because such comparisons can alter responses. Specifically, direct comparison of nearly identical stimuli can exacerbate differences in outcomes because when stimuli are nearly identical a small difference will drive the participant's choice, or reduce them because a direct comparison makes the socially desirable choice more salient. A way to address these concerns is to limit the study to participants who receive many similar correspondences so the stimuli are just two (or more) of many and are thus less likely to be directly compared, although this could limit the external validity of the study. To further mitigate concerns about multiple correspondence, all stimuli features can be varied within reasonable limits (i.e., change more than just the name of the putative stimuli writer), when possible send stimuli that are not directly comparable (e.g., FOIA request vs simple ask about unrelated issue), and send stimuli at separate times.

A common problem with audit studies across all fields, not just in PA, is when researchers do not ensure their stimuli are externally valid. In some cases, they end up testing not what they think they are testing, but testing the unusual. Examples from economics might be showing pictures on resumes in countries where such things are uncommon, or omitting education information when education is always shown on resumes. More subtle versions of this problem occur when, for example, using names to signal race, gender, or ethnicity, because names also signal age, socioeconomic status, and potentially citizenship status (Einstein & Glick 2017; Barlow & Lahey 2018; Gaddis 2017a, b; Landgrave 2021; Crabtree et al. 2023) Similarly, a potential concern related to the external validity of the Y variable is pointed out by Olsen et al. (2022)—just as the request for an interview is only the first stage of the hiring process and does not measure actual hiring, the provision of information about a service does not measure actual service provision, although it is still the first step. Finally, when researchers send out limited templates, as discussed in the introduction, they may be subject to template bias—that is, their findings will only be externally valid for the groups that the templates describe.

Ethics

Ethical concerns with audit studies derive from academic concerns about deception to negative spillovers on constituents by taking away time from and potentially providing incorrect information to public servants. While it is beyond the scope of this paper to provide a full framework of the ethics of audit studies, a general guiding principle is that the benefits to audit studies should always be greater than any potential harm. In practice, this principle generally means that researchers need to be careful of participant time, make sure data are anonymized so that no participant can be called out, and if there is a chance of potential harm from providing false information then the response should be followed up with a post-consent form. If these precautions cannot be taken, then an audit study may not be an appropriate tool. New methods of combining audit technologies with real, rather than hypothetical, stimuli are a promising path forward.

While deception is common in psychology experiments, it is frowned upon in economics experiments if the subjects know they are participating in a study. Experimental economists believe that their subject pool should never try to second guess the purpose of the experiment (e.g., Davis & Holt 1993, Ortman & Hertwig 2002). Deception in any economics experiment in which subjects know they are participating would have negative spillovers on this goal. Audit studies circumvent this problem because the participants generally do not know that they are participating in the experiment (McClendon 2012; James et al. 2017).

There is some evidence that the subject pool of politicians and constituents does not find these types of experiments to be problematic (Naurin & Öhberg 2021). That said, deception is commonly considered unethical and is considered by some to have unknown societal costs including to political behaviors (Findley & Nielson 2016; James et al. 2017). Findley & Nielson (2016) reports a pair of studies showing that some degree of deception is necessary for unbiased results that may provide considerable policy implications. They also provide suggestions on how to reduce (but not necessarily eliminate) deception including informed consent and recruiting confederates that write the stimuli using their own names and contact information to avoid identity deception. Landgrave (2020) echoes the suggestion for using confederates, and proposes a novel study design that avoids identity, activity, and misinformation deception by stating up front that the contact is for research and then analyzing responses interacted with the incentivization characteristics.

Ethically, the researcher has an obligation to minimize the harm done to unwitting participants. Experiments that require a lengthy response should only be done if the benefit outweighs the cost. Data should be anonymized—no individual participant should be able to be called out as biased (this warning is particularly important for public university researchers who may be subject to FOIA requests for their research data). With PA experiments, in addition to the direct costs to the participants, there may be negative spillovers if responding to the audit study distracts participants from real constituent requests and duties or causes them to inaccurately change their beliefs about constituent priorities. These concerns should be included in the cost-benefit calculation.

Decisions to post-consent participants should be weighed carefully—on the one hand, post-consenting makes participants aware of the deception of the experiment and could make participants suspicious of future interactions with real constituents. It is possible that an agency discovering the deception could additionally provide negative reputational consequences to the research team and university.^{viii} On the other hand, participants gather information from and can be otherwise affected by the deceptive communications. If it is likely they will make decisions based on these communications or suffer any harm from believing the deception, then the post-consent is necessary to mitigate that harm. The post-consent should also include the ability for participants to remove their data, giving participants a locus-of-control if they did not want to participate.

We find that 47/90, or a little over 50% of studies discuss ethical implications of their study process, though nine of these limit their discussion to an appendix only, rather than the main paper. While absence of a discussion does not mean that ethical concerns were not taken into consideration, explicitly stating the measures taken to reduce harm in a study is helpful for readers and future researchers.

Perhaps the ideal audit study reduces deception and/or loss of participant time by combining an experiment with real outputs that will be used for another purpose (e.g., Block et al. 2021; Grose et al. 2015; Landgrave 2020; Peisakhin & Pinto 2010). A recent study from economics pairs real college students requesting advice from working professionals to study the effects of gender on career advice (Gallen & Wasserman 2021). In PA, this type of combination could translate to FOIA audit studies requesting information that they need for another study (e.g., Jenkins et al. 2020; Spáč et al. 2018). Similarly, researchers studying the effect of

the personal demographics of fundraisers could partner with a non-profit that benefits from the donations (Jilke et al. 2019; Landgrave 2020). In addition, working with existing organizations is one way researchers planning audit studies can find collaborators and focus research on topics relevant to political agents. For example, while not an audit study because the focus was on changing behavior rather than measuring it, Bergner, Desmarais, & Hird (2019) increased the impact of their field experiment by partnering with an advocacy group.

The future of audits

As email and electronic messaging platforms become the primary modes of communication, both the ease of performing an audit study and their potential scope continue to grow. Even though some of the increased ease of communication may be of limited use in PA (e.g., Google ads would be an ineffective medium to study elite lawmakers), there will be an overall increase in feasibly explorable theories and questions about practices in PA. There will be new opportunities to reach different offices of governing agencies, broader coverage of governing bodies with smaller geographic reach (e.g., county or city governments, such as Spáč et al. 2018 which studied all Slovak municipalities), and, on the other side of the scale, increased ease of international studies (e.g., 11 countries are compared in Magni & Ponce de Leon 2021). Reaching sufficient sample size for expected effect sizes (e.g., 10,268 government representatives were emailed in Crawford and Ramli 2022) and engaging a sufficient variety of participants (e.g., both elected officials and the general public were studied in Block et al. 2021) should become more manageable with increased use of digital communication. By reaching more participants, the time cost for individual participants can be minimized, for example, sending fewer stimuli per participant or dividing one complex “ask” into multiple stages with different participants per stage.

Digital communications also make sending multiple stimuli to the same participant simple, inexpensive, and quick, so within-subjects and follow-up studies are also getting easier to perform with broader scope. Within-subjects studies can provide more statistical power that may be necessary when the pool of participants is small (e.g., political elites), while follow-up studies (e.g., Butler & Crabtree 2017) investigate the effects of an initial stimulus on the participant’s response to a subsequent stimulus.

Simultaneously, the ongoing trend towards digital communications favors more intricate stimuli designed to detect how responses might be influenced by more complex relationships between stimulus and participant characteristics. Various audits have shown that intersections between characteristics in a single stimulus (e.g., race crossed with age) or between the stimulus and the participant (e.g., gender of stimulus crossed with gender of participant) are important (e.g., Habel & Birch 2019; Druckman & Shafranek 2020; Rhinehart 2020). Studies with sufficient participants to support diversification of the stimuli will benefit from the increased ease of creating and distributing balanced stimuli that explore more such interactions, thus providing a fuller exploration of the market.

In other fields, audit studies have commonly been used to explore the hiring market and the housing market, typically exploring discrimination based on some characteristic that varies between stimuli, such as using the name to indicate race. These fields have recently called for broader use of the audit study method to understand different markets. At the same time, these fields have demonstrated that researchers need to be more careful that their characteristics actually signal what they think is signaled. Additionally, there has been a push to go beyond documenting the existence of discrimination to identifying its mechanisms, e.g., through side-by-side use of an audit study and a lab experiment or survey exploring hypotheticals, or by taking advantage of natural experiments (Gaddis 2018). Each of these three areas is of note for the future use of audit studies in PA: explore new markets, be careful about internal and external validity, and push for a deeper understanding of the market.

Acknowledgment

Thanks to Jaqueline Mendez, Lala Taghiyeva, Zakary Piwetz, Brady Duke, Ngoc-Nhu Vo, Karen Gracia, and Gabriela Bazan for excellent research assistance.

Notes

ⁱ There are many purposes of systematic literature reviews. We are using the first listed purpose of a systematic literature review from (Page et al. 2020, p. 1), to “provide syntheses of the state of knowledge in a field, from which future research priorities can be identified.” We are hoping to provide information to PA researchers about the field of audit studies within the broader area of public administration that could be considered “public service” (in which we also include politicians and non-profits).

ⁱⁱ Some papers in the review will have later final publication dates because they were cited while working papers or they were published online prior to a later publication date in the paper version of the journal. The following unpublished papers would have been included if they had been published: De Vries, Dinas, & Solaz 2016; Janusz & Lajevardi 2016; Mendez 2014; Mikula & Montag 2022; and Timm 2021.

ⁱⁱⁱ We thus only caught audit studies from general interest journals if they cited or were referenced by prominent papers or literature reviews of PA audit studies.

^{iv} Other literature reviews of field experiments more generally include Bertrand and Duflo (2017), Neumark (2018). Meta-analyses on audit studies using racial discrimination specifically include Quillian et al (2017) and Gaddis et al. (2021).

^v It is not our intention to discourage researchers from using standard stimuli. There is still much to be learned from standard stimuli.

^{vi} One potential concern is that studies may be subject to post-treatment bias if instead of just looking at number of responses, they explore the quality of responses, as measured by speed of response or tone of response.

^{vii} Gaddis et al. (2021) discuss the cost-benefit analysis of ethical concerns in more detail.

Appendix B: Summarized Results

Paper citation	Results
Adman, Per, and Hanna Jansson. 2017.	Swedish-sounding names were replied to in a friendlier, more welcoming way than were Arabic-sounding names.
Alizade, J., R. Dancygier and R. K. Ditlmann. 2021.	Signals of national identification and attachment do not affect responsiveness. Politicians are 50% more likely to assist a large low-status group (Turks) than a small high status-group (Canadians).
Bárcena Juárez, S. A. and Y. P. Kerevel. 2021.	Legislators are more responsive to individual citizens when they are being contacted about high-profile, salient policy issues, and when they have the relevant experience and staff resources to attend to individual requests.
ben-Aaron, J., Denny, M., Desmarais, B. and Wal-lach, H. 2017.	Peer conformity affects both in the time to initial response and in the rate of complete request fulfillment.
Block, R., C. Crabtree, B. Holbein John and J. Q. Monson. 2021.	In electronic interactions, on average, the public is less likely to respond to emails from people they believe to be Black (rather than White).
Bol, D., Gschwend, T., Zittel, T., & Zittlau, S. 2021.	Legislators treated with a personal vote intention were more likely to respond (67 percent) and respond faster than those treated with a parti-san vote intention (59 percent). The treatment effect is moderated by electoral system incentives: it is larger for nominally-elected legislators than for those elected via a party list.
Broockman, D. E. 2013.	Nonblack legislators were less likely to respond when their political incentives to do so were diminished. Black legislators typically continued to respond even when doing so promised little political reward. Black legislators thus appear substantially more intrinsically motivated to ad-vance black interests.
Brown, J. R. and H. Hilbig. 2021.	Prospective applicants with criminal records are about 5 percentage points less likely to receive information from college admission offices. There is no difference in response rates to Black and White applicants. Discrimination against formerly incarcerated applicants is driven by private schools. No evidence is found that advocate endorsements decrease bureaucratic bias.
Butler, D. M. and C. Crabtree. 2017.	White, local elected officials are less responsive to black constituents.
Butler, D. M., & Broockman, D. E. 2011.	White legislators of both parties exhibit similar levels of discrimination against the black alias. Minority legislators do the opposite, responding more frequently to the black alias. Putatively black requests receive fewer replies. Putatively black alias continues to be differentially treated even when the emails signal partisanship.
Butler, D. M., Karpowitz, C. F., & Pope, J. C. 2012.	Both state and federal legislative offices are more responsive to service requests than they are to policy requests. At the federal level, Demo-crats prioritize service over policy more than Republicans and at the state level legislators who won by larger margins are more likely to priori-tize service over policy.
Butler, Daniel M., Catherine E. De Vries, and Hec-tor Solaz. 2019.	Local officials do not exhibit a bias toward seeking out information on the policy experiences of local governments in one's own country as opposed to governments outside of the country. They do not exhibit a bias against information about policies that have received an EU en-dorsement.
Carnes, N. and J. Holbein. 2019.	Officials were equally likely to respond regardless of the constituent's class.
Chen, Jidong, Jennifer Pan, and Yiqing Xu. 2016.	At baseline, approximately one-third of county governments respond to citizen demands expressed online. Threats of collective action and tattling to upper levels of government cause county governments to be more responsive, whereas identifying as loyal, long-standing members of the Chinese Communist Party does not increase responsiveness. Threats of collective action make local officials more publicly responsive.
Crawford, L. and U. Ramli. 2021.	Response rates are six to seven percentage points lower to stereotypically Muslim or Jewish names. The two major political parties both show equal bias towards the two minority group names. Bias is lower in more dense and diverse locations.
Darolia et al., 2015.	No evidence that employers prefer applicants with resumes listing a for-profit college relative to those whose resumes list either a community college or no college at all.

Dhima, K. 2020.	Legislators are more responsive to female political aspirants and more likely to provide them with helpful advice. This pro-women bias, which exists at all levels of government, is stronger among female legislators and those associated with left-leaning parties.
Diltmann, R. K. and P. Lagunes. 2014.	Latinos were asked to present an identification card (ID) more frequently than Anglo customers, were quoted a higher minimum-dollar amount for purchasing a gift certificate, and received more negative affect from salespersons. Among those who were asked for identification, a municipal-issued ID card was declined at equal rates from Latinos and Anglos, while an unofficial ID card was declined more from Anglos than Latinos.
Dinesen, Peter Thisted, Malte Dahl, and Mikkel Schiøler. 2021.	Ethnocentric responsiveness is observed with no indication that electoral incentives mitigate this behavior. However, minority voters can use parties' and individual candidates' stances on immigration to identify responsive politicians.
Distelhorst, G. and Y. Hou. 2017.	Local service institutions in China are comparably responsive to appeals from putative citizens as similar institutions in democracies.
Distelhorst, G., & Hou, Y. 2014.	Local officials were 33% less likely to provide assistance to citizens with ethnic Muslim names than to ethnically-unmarked peers. Evidence is consistent with the ingroup bias interpretation of this finding and detect little role for strategic incentives mediating this effect.
Driscoll, Amanda, Gabriel Cepaluni, Feliciano de Sá Guimarães, and Paolo Spada. 2018.	Distinguishing between prejudiced and strategic discrimination in responsiveness, we find that socioeconomically privileged and competitive candidates are equally responsive to underrepresented voters in advance of the election, yet less responsive once in office.
Dropp, K., & Peskowitz, Z. 2012.	Legislators' response rates to constituent requests decreases in their electoral security. Electoral security increases the number of bills legislators author, but has little effect on other measures of legislative production.
Druckman, J. N. and R. M. Shafranek. 2020.	No direct evidence of a racial or political bias. African Americans who reference politics in any way receive substantially fewer responses.
Dynes, Adam M., Hans J. G. Hassell and Matthew R. Miles. 2021.	Politically ambitious officials are not more responsive to electorally oriented service requests and there are not systematic differences in the content of the responses of ambitious and non-ambitious elected officials. In areas of constituency service, ambition does not seem to affect representational behavior, regardless of whether the service requests are electorally related or not.
Einstein, K. L., & Glick, D. M. 2017.	Public housing officials respond at equal rates to black and white email requests. Limited evidence of responsiveness discrimination toward Hispanics. Substantial differences in email tone. Hispanic housing applicants were 20 percentage points less likely to be greeted by name than were their black and white counterparts. This disparity in tone is muted in more diverse locations, but does not depend on whether a housing official is Hispanic.
Epstein, B., L. Bode and J. M. Connolly. 2021.	Overall, municipalities responded to 54% of email requests and 38% of Twitter requests. A majority of responses were received on the same business day. Responses are slightly faster on Twitter, but of higher quality on email. Governments are more likely to respond to frustrated constituents on email, but respond faster to frustrated queries on Twitter, though with lower quality responses.
Ernst, R., Nguyen, L., & Taylor, K. C. 2013.	Consistent relationships between race and the quantity of information received and the quality of the interaction with the representatives of the state. Evidence that the state reinforces notions of both belonging and marginalization through patterns of racialized encounters with the state.
Fang, Albert H., Andrew M. Guess and M. Humphreys. 2019.	Hispanics are approximately 6 percentage points less likely to receive callbacks and offers than whites. Suggestive evidence that government messaging can reduce discrimination against Hispanics but not against blacks.
Fenton, J. and L. Stephens-Dougan. 2021.	Black legislators were as responsive to emails referencing inspiration from BLM as they were to emails referencing inspiration from the NAACP.
Findley, Michael G., Daniel L. Nielson, & J. C. Sharman. 2015.	Firms in tax havens obey the rules significantly more often than in OECD countries, whereas services in poor nations sometimes prove more compliant than those in rich countries. Risk of terrorism or the Internal Revenue Service decrease offers for anonymous incorporation, but they also lower compliance. Offers to "pay a premium" reduce compliance. The risk of corruption decreases response rates but, alarmingly, also decreases compliance rates. Raising international law has no significant effect.
Gaikwad, N. and Nellis, G. 2021.	Signaling that a citizen is a city newcomer, as opposed to a long-term resident, causes incumbent politicians to be significantly less likely to respond to requests for help.

Gell-Redman, M., Visalvanich, N., Crabtree, C., & Fariss, C. J. 2018.	Nativity and voting status do not affect responsiveness. Instead, legislator behavior appears to be driven by racial/ethnic bias. Whites benefit from the highest degree of responsiveness, with blacks, Hispanics, and Asians all receiving lower response rates, respectively. This bias follows a partisan logic. Hispanic constituents receive lower responsiveness primarily from Republican legislators, while Asians experience discrimination from representatives of both parties.
Giger, N., S. Lanz and C. de Vries. 2020.	High response rate among Swiss candidates (66 percent) which remains high for voters who reside outside a candidate's district (59 percent) suggesting that intrinsic motivations are a key driver of constituency effort. The response to voters who reside inside a candidate's district is more pronounced for candidates confronted with a high degree of electoral competition.
Giulietti, C., M. Tonin and M. Vlassopoulos. 2019.	Emails from putatively black senders are almost 4 percentage points less likely to receive an answer compared to emails signed with a white-sounding name. Moreover, responses to queries coming from black names are less likely to have a cordial tone. The differential in the likelihood of answering is due to animus toward blacks rather than inferring socioeconomic status from race.
Golder, S. N., Crabtree, C., & Dhima, K. 2019.	Our results show that elected officials are equally willing to respond to both male and female political aspirants.
Grimmelikhuijsen, S., John, P., Meijer, A., & Worthy, B. 2019.	The overall response rate of local governments was much higher (76%) and the size of the effect was larger than in the original experiment. Furthermore, the strongest effect of FOI was found on proactive disclosure (concordance).
Grohs, S., Adam, C., & Knill, C. 2016.	Local German government responses show very limited discrimination effects. While there is no evidence for general ethnic discrimination, a more differentiated analysis indicates patterns of ethnic discrimination conditioned by gender.
Grose, C. R., Malhotra, N., & Parks Van Houweling, R. 2015.	Most senators tailor their explanations to their audiences, and these tailored explanations are effective at currying support—especially among people who disagree with the legislators' roll-call positions.
Habel, Philip, and Sarah Birch. 2019.	On average, 9% of emails go without a personal reply from MPs or their staff. Did not observe statistically significant differences across our manipulation for class or for ethnicity. Ingroup identifiers that could provoke taste-based discrimination or professional markers signaling a higher propensity to turn out, did not generate statistically significant patterns of representation. There was an interaction effect between occupation and ethnicity, with greater divergence in ethnicity-based responsiveness for putatively lower-class constituents than for higher-class constituents. MPs from safer seats were slower to respond, but additional factors such as party, the gender of the MP, or characteristics of the constituency were not statistically significant predictors.
Hayes, T. J., & Bishin, B. G. 2020.	There is no evidence that members of Congress discriminate by economic class and only mixed evidence that state legislators discriminate along these lines. There is limited, but potentially important, evidence of partisan bias in service responsiveness for state legislators.
Hemker, J. and Rink, A. 2017.	Response rates are statistically indistinguishable across treatment conditions. Putative non-Germans receive responses of significantly lower quality, potentially deterring them from applying for benefits. Observational evidence suggests that discrimination is more pronounced in welfare offices run by local governments than in those embedded in the national bureaucracy.
Hou, Y., Liu, C., & Crabtree, C. 2020.	Results show that a Muslim job seeker is more than 50% less likely to receive a callback than a Han job seeker, and higher academic merit does not compensate for this bias. State-owned enterprises are equally likely to discriminate against Muslim job seekers, despite their political mandate to increase diversity.
Hughes, Alex, et al., 2020.	Bias toward Latinos observed during the 2012 election has persisted. Arab/Muslim Americans face an even greater barrier to communicating with local election officials, but there is no evidence of bias toward blacks. There is evidence of implicit bias toward Arab/Muslim senders only.
Jenkins, Nicholas R., Michelangelo Landgrave, Gabriel E. Martinez. 2020.	There is no evidence that political donors have greater access to government officials compared to engaged citizens. A formal FOIA request increases compliance rates and decreases wait time before an initial reply.
Jensen, Nathan M., Michael G. Findley, & Daniel L. Nielson. 2020.	There is no greater tendency to offer incentives for investment anticipated prior to than after elections. Limiting the sample to municipalities that specialize in manufacturing, the relevant subgroup, suggests that election timing matters in this most likely set of locales.

Jilke, S., Lu, J., Xu, C., & Shinohara, S. 2019.	Providing information about government support to nonprofit organizations neither increases nor decreases people’s propensity to donate.
Jilke, S., Van Dooren, W., & Rys, S. 2018.	No statistically significant differences between senders were found for overall response rates. Privately owned facilities are about 20 percentage points less likely to provide information on how to enroll when the request is sent from a Maghrebian name alias, and blinded coders perceive the information sent to the Maghrebian alias as less comprehensive. In publicly owned facilities, no such differences exist.
Kalla, Joshua L., and David E. Broockman. 2016.	When informed prospective attendees were political donors, senior policy makers made themselves available between three and four times more often.
Kalla, Joshua, Frances Rosenbluth, and Dawn Langan Teele. 2018.	Emails sent by female students were more likely to receive a response than those sent by male students, especially when the official was male. Responses that women received were as likely to be long, thoughtful, and contain an offer of help as those to men. There were no partisan differences in responsiveness to male or female senders. Examining senders with Hispanic last names bolsters the results: Hispanic senders, especially men, were less likely to receive a quality response than non-Hispanic senders.
Lagunes, P., & Pocasangre, O. 2019.	Entities do not discriminate between regular and seemingly influential citizens. Entities also answer more frequently and provide more information in 2015 compared to earlier years, but they are taking longer to answer, frequently charging fees, and often failing to provide quality information to questions they are legally bound to answer.
Landgrave, M. 2020.	There is evidence of discrimination against Hispanics among state legislative offices. That discrimination is mitigated when subjects believe their behavior will be public knowledge.
Landgrave, M. 2021.	Hispanics and whites receive similar constituency service, as measured by reply rate and reply content, but legislators are less likely to acquire information about Hispanic constituents.
Landgrave, M. and N. Weller. 2022.	Low SES status is related to reply rates both across and within each racial category.
Larsson Taghizadeh, J., Åström, A., & Adman, P. 2022.	There are no clear signs of discrimination towards voters with Arabic- or Swedish-sounding names.
Lloren, A. 2017.	Direct democracy does not enhance Swiss state politicians’ responsiveness to policy requests.
Loewen, P., & MacKenzie, M. 2019.	On average, politicians are as helpful on issues of shared jurisdiction as issues of exclusive jurisdiction. They are less helpful for issues outside of their jurisdiction.
Lowande, K., & Proctor, A. 2020.	There is no evidence of systematic discrimination against same-sex couples. Among same-sex couples, officials tended to be more responsive to lesbian couples.
Magni, G., & de Leon, Z. P. 2021.	Legislators respond significantly more to women (3% points), especially in Europe (4.3% points). In Europe, female legislators in particular reply substantially more to women (8.4% points).
McClendon, G. H. 2016.	South African politicians—both black and white—are more responsive to same-race constituents than to other-race constituents, in both the dominant and the main opposition political parties. Politicians are not particularly responsive to anyone.
Mendez, M. S., & Grose, C. R. 2018.	If legislators supported voter identification laws, Latino constituents were less likely to receive constituency communications from their legislators.
Michelson, M. R. 2006.	Latino and non-Latino canvassers are equally likely to cause Latinos to turn out to vote.
Michener, Gregory; Velasco, Rafael B.; Contreras, Evelyn; Rodrigues, Karina F. 2020.	Results show institutional requesters receive one-fifth more responses than noninstitutional comparators. For moderate versus lower burden requests, noninstitutional requesters are 11% less likely to receive a compliant response than their institutional comparators.
Moy, B. J. 2021.	No evidence that mayors are affected by priming the officials’ duty to the public. The mayors who received the peer effects prime were 6–8 percentage points less likely to respond.
Nazita Lajevardi. 2020.	Socioeconomic status does not matter for Muslims—whites receive more responses regardless of SES—and party affiliation does not affect response rates. Imams are significantly less likely than their Pastor counterparts to receive a response.

Neiman, J. 2017.	Communication from constituents with lower education levels receive fewer replies. Neither political party nor legislator's own education level account for the response differential to the email manipulations.
Newland, Sara A., and John Chung-En Liu. 2020.	Officials are equally responsive to requests putatively from indigenous or ethnically Chinese citizens.
Oberfield, Z. W. and M. B. Incantalupo. 2021.	Street Level Managers (SLMs) discriminated based on race, and positive performance information mitigated this discrimination. Negative performance information also reduced discrimination. There is no evidence that less public organizations (charter schools) exacerbated anti-Black discrimination. White SLMs discriminated against Black citizens. However, Black SLMs worked in more administratively difficult settings and responded at lower rates; thus, Black citizens were equally likely to receive responses from White and Black SLMs.
Olsen, A. L., Kyhse-Andersen, J. H., & Moynihan, D. 2020.	Danes and Muslims received similar response rates. Danes received a clear acceptance 25% of the time, compared to 15% for Muslims. Muslims also faced greater administrative burdens in the form of additional questions.
Peisakhin, L. 2012.	Applicants who make use of the freedom-of-information law attain almost the same rate of success as those who bribe.
Peisakhin, L. and P. Pinto. 2010.	Greater transparency and voice lowers corruption even in highly hierarchical and unequal societies.
Pfaff, S., Crabtree, C., Kern, H. L., & Holbein, J. B. 2021.	Muslims and atheists are substantially less likely to receive a response, with discrimination growing when they signal that their beliefs are more intense. Protestants and Catholics face no discrimination unless they signal that their religious beliefs are intense.
Poole, Ed Gareth., 2019.	FOIA requests identify significant variation in timeliness and quality between UK territories. There is a lack of evidence that lower-tier governments are generally more responsive.
Porter, E., & Rogowski, J. C. 2018.	Overall, partisan email-writers were somewhat more likely to receive responses from local election clerks than email-writers who provided no partisan signal, though these effects are driven mostly by greater responsiveness to Republican constituents. There is some evidence of increased responsiveness to requests from copartisan constituents, particularly among Republican municipalities. There is no evidence that local institutional context moderates the effects of the partisan treatments.
Rhinehart, S. 2020.	Legislators are more willing to offer help when the aspirant is a woman and of the same party. When primed to further consider women in politics, legislators are more likely to offer gender-specific advice. Democrats rather than women legislators drive this heightened responsiveness to the woman aspirant.
Rochlitz, M., E. Mitrokhina and I. Nizovkina. 2021.	Switching the political affiliation of a potential investor from the opposition party "Yabloko" to the government party "United Russia" on average increases the chances to receive a reply by 30%. The effect strongly depends on regional levels of political competition, with higher levels of discrimination in regions that are less politically competitive.
Rodríguez, Rafael Piñeiro, and Cecilia Rossel. 2018.	Only those citizens who know the RTI law and invoke its existence have a greater likelihood of obtaining an answer from bureaucrats. This result is driven mostly by men's requests declaring they know the law when making their request, while invoking the law doesn't make a difference in responses to women.
Sonia K. Kang, Katherine A. DeCelles, Andrés Tilcsik, & Sora Jun. 2016.	Organizational diversity statements are not associated with reduced discrimination against unwhitened resumé.
Southern, R. and K. Purdam. 2016.	More than half of electoral candidates responded to an undecided voter's email. Very few provided followup emails.
Spáč, P., P. Voda and J. Zagraban. 2018.	Referring to FOI acts leads to several times higher odds in receiving the requested information. Including a moral appeal in the information request has no effect. With rising population, the responsiveness for all versions of letters increases.
Sun, T. 2019.	At the local level, differentiation in local government treatment of CSOs (civil society organizations) is driven more by the state's interest in extracting productivity and out sourcing responsibility for the provision of public goods and less by the state's need to acquire information from CSOs, including politically sensitive advocacy groups.
Taghizadeh, Jonas L. 2021.	Principals who perceived that they had sufficient time to respond to emails were less likely to discriminate towards the Arabic and low-SES parents.

Terechshenko, Z., Crabtree, C., Eck, K., & Fariss, C. J. 2019.	There is a positive effect of international norms on state respect for human rights. The potential of international shaming does not increase the probability of state compliance. The positive effect of the norms cue disappears when it is coupled with the shaming cue.
Thomsen, Danielle M., and Bailey K. Sanders. 2019.	Women are more likely to respond to constituent requests than men, even after accounting for their heightened level of policy activity. Female legislators are the most responsive in conservative districts, where women may see the barriers to their election as especially high. Findings are not a function of staff responsiveness, legislator ideology, or responsiveness to female constituents or gender issues.
Vaishnav, M., Khosla, S., Milliff, A., & Osnos, R. 2019.	There is scant evidence of legislators discriminating on religious lines.
Vuolo, Mike; Lageson, Sarah; Uggen, Christopher. 2017.	(1) Among the 78% of employers who ask about records, specific application questions vary greatly regarding the severity and timing of offenses. (2) Applications for restaurant positions are least likely to inquire about criminal histories, whereas racially diverse workplaces and establishments in the most and least advantaged neighborhoods are more likely to ask. (3) The race gap in employer callbacks is reduced when applicants have the chance to signal not having a record by answering "no," which is consistent with theories of statistical discrimination.
Wagner, A. J. 2021.	The results suggest significance in race and political variables in FOI outcomes and processes. The influence of geographic location, namely the central South of the United States, has a considerable effect on FOI compliance.
White, A. R., Nathan, N. L., & Faller, J. K. 2015.	Officials provide different information to potential voters of different putative ethnicities. Emails sent from Latino aliases are significantly less likely to receive any response from local election officials than non-Latino white aliases and receive responses of lower quality.
Wiener, E. 2020.	Women are twice as likely to respond to a women's issue group's simple meeting request. Meeting requests signaling constituent mobilization have heterogeneous effects across legislator gender, doubling the likelihood that a male legislator will respond and effectively closing gender gaps in responsiveness.
Worthy, B., John, P., & Vannoni, M. 2017.	FOI requests are more effective than simple asks and the size or preexisting level of openness of a body appears to make little difference to their responsiveness. FOI requests are more effective in encouraging bodies to do more than the law asks (concordance) than encouraging more minimal levels of legal cooperation, when a body simply fulfils its obligations to varying degrees (compliance).
